

Zelená Vinice

FRAMER WEBSITE TEMPLATE

Zelená Vinice — Setup Guide

A restaurant website template that ships in two forms: a Framer code component you edit visually, and a standalone HTML page you can host anywhere. Both render the same design.

Version 11 · Full guide

1. What's in the package

FOLDER / FILE	WHAT IT IS
<code>ZelenaViniceSite.tsx</code>	The Framer code component. You do not need this if you opened your link — it is here for putting the site into a Framer project you already have.
<code>zelena-vinice-mockup.html</code>	The full site as one standalone HTML file. Open it in any browser or upload it to any host.
<code>photos/</code>	The five photographs from the demo — one hero shot and four dishes.
START HERE.pdf	The one-click duplicate link, and the manual route. Read this first.
Full guide.pdf	This guide.

You need a Framer account to use the `.tsx` file. The `.html` file needs nothing at all — it runs on its own.

2. Framer setup

Your site arrives ready. The link in **START HERE.pdf** opens it straight into your Framer account — the component already placed, every section filled in, the photographs in place. There is no code to copy, and this is the route the template is built around.

Everything from there is done in the properties panel on the right, and the rest of this guide is about that panel.

The steps below are only for the other case: putting the component into a Framer project you have already built.

1. Open your Framer project.
2. In the Assets panel, click **+** → **Code File**, and name it `ZelenaViniceSite`.
3. Delete the placeholder code, then paste in the whole contents of `ZelenaViniceSite.tsx` and save.
4. Drag the component from the Assets panel onto your canvas.
5. Set its width to **Fill**. Height is handled by the component itself and shows as **Fit** — leave it.
6. Everything is now edited from the properties panel on the right.

If the panel looks empty

Select the component itself, not the frame around it. The controls only appear when the component instance is selected.

If a setting you expect is missing

The first field in the panel is **Version**. It should read `v11 · multi-line fields`. If it shows something older, you are looking at an older build of the component — which can only happen on the manual route above, where a code file with an error keeps serving the last working one. Paste the file again and save.

3. How the controls are organised

The properties panel is split into twelve groups, in the order the sections appear on the page:

Every content section starts with a **Show** switch. Turn a section off and it disappears from the page — nothing else shifts or breaks. A one-page card for a bistro and a full seven-section site come from the same component.

4. Writing more than one line in a field

This is the one thing worth knowing before you start.

Framer's properties panel commits some multi-line fields the moment you press Enter, instead of inserting a line break. Opening hours and addresses then sit stubbornly on one line however hard you lean on the key.

Type a `|` where you want the break.

Mon–Thu 11:00–23:00|Fri–Sat 11:00–24:00|Sun 11:00–22:00

renders as

Mon–Thu 11:00–23:00
Fri–Sat 11:00–24:00
Sun 11:00–22:00

A real line break still works wherever the field lets you make one. The two mean exactly the same thing and you can mix them freely.

This works in five places:

WHERE	WHAT A  DOES
 Find us → Address	new line
 Find us → Opening hours	new line
 Reservations → Hours	new line
 Hero → Headline	new line
 About → Text	new paragraph

Nothing else splits the text. Commas and semicolons are ordinary punctuation, so `Národní 15, 110 00 Praha` stays on one line, and a sentence with a semicolon in it stays one sentence. Spaces around the `|` are tidied up, and an accidental `||` does not leave a gap.

5. Colour

Open  **Colors. Theme** carries five complete palettes:

THEME	FEEL
Garden	The green and gold of the demo. The default.
Cellar	Dark, warm, candle-lit.
Terracotta	Clay, rust and cream.
Linen	Muted green-grey, quiet and formal.
Midnight	Deep blue with a brass accent.

Your own colours sit on top of the theme

Under the theme picker are ten colour fields, each with a checkbox. Tick one, choose a colour, and **only that colour changes** — everything you leave unticked keeps following the theme.

So you can take **Cellar**, set the accent to your own gold, and later switch to **Midnight**: the whole page moves, your gold stays. Set all ten and nothing is left of the theme.

Everything else is derived and never has to be set by hand: button hover and active states, borders, shadows, the glow behind the page, the tint on the map, the frosted panels, the wash over the hero

photograph, and the gradient under each menu tile's name.

Ignore my colors puts the theme back in one click without unticking each field. Your picks stay stored — switch it off and they return.

6. Type & spacing

 **Type & spacing** holds the two typefaces, the content width, the spacing between sections, the corner radius, and the frosted-glass effect.

The fonts load from Google Fonts through the **Fonts URL** field. To use different typefaces, pick them on fonts.google.com, copy the URL from the embed snippet into that field, and write the family names into **Heading font** and **Body font**. Turn **Load web fonts** off if you would rather use fonts you have already added to your Framer project.

Frosted glass switches the translucent panels to solid ones. Worth trying if the page feels busy, or if you are printing screenshots.

7. Header and the slide-out menu

 **Header** holds the restaurant name — split into two fields so the second word takes the accent colour — the navigation links, the button, and two switches: whether the header stays on top as you scroll, and whether the menu button appears.

Links understand two kinds of address. `#menu`, `#about`, `#gallery`, `#location`, `#reserve` and `#top` scroll to that section of the page; anything starting with `http` opens as an ordinary link.

≡ **Slide-out menu** is the panel behind the menu button, with its own list of links, each with an icon from a dropdown of 35.

On a phone the navigation links hide and the menu button takes over, which is why the slide-out list is worth filling in even if you do not use it on desktop.

8. Hero

 **Hero** takes a **Photo** or a **Video** — the video wins if both are set, and plays muted on a loop. Then the eyebrow, the headline, the paragraph and two buttons.

Overlay decides the dark wash over the photograph that keeps the writing readable. Left on **Follow theme** it is mixed from the palette, so it repaints when you change theme. Choose **Pick my own** to set it by hand.

Overlay strength is how dark that wash is: lower it for a dark photograph, raise it for a bright one. **Blur behind text** softens the picture under the words. **Parallax** drifts the photograph as the page scrolls.

On a phone the hero stacks: the photograph on top, the writing below it on a dark panel.

9. Menu

 **Menu → Categories** is the list of tiles. Each tile is its photograph, with the category name over the bottom-left corner. Tapping one opens a panel with every dish in it.

Each category has:

- **Name** — what appears on the tile
- **Photo** — fills the whole tile
- **Icon (no photo)** — used when there is no photograph
- **Caption** — the small line under the name. Empty by default; type something ("6 dishes", "seasonal") and it appears.
- **Dishes** — its own list, opened from the same row

A category with no photograph is not left looking unfinished: it becomes a pale tinted card with its icon and the name in your title colour.

Each dish has a name, a description, a price, an icon from the same dropdown, and an optional **Card tint** if you want to mark one out.

The dish panel takes almost the whole screen on a phone and uses a larger type scale than the desktop one — a menu is read at arm's length. It scrolls inside itself, so a category with twenty dishes fits as happily as one with four.

10. About and Gallery

 **About** is a heading, the text, and either a photograph or an icon. Separate the paragraphs with a  (see section 4).

 **Gallery** is a list of tiles, each either a photograph or an icon. Add and remove rows freely — the grid closes up around whatever is there.

11. Find us

 **Find us** holds the restaurant name, the address, the opening hours, the phone number and a line about getting there. Remember the `|` for the address and the hours.

Map offers three routes:

- **From address** builds a Google Maps embed from what you type into **Map address** — no account and no API key. It falls back to the address above if you leave it empty. **Zoom** and **Map language** tune it.
- **Pasted embed** takes whatever you copy from Google Maps' *Share → Embed a map*. Paste the entire `<iframe ...>` snippet; the address inside it is found for you.
- **No map** drops the frame and lets the details span the card.

Tint map washes the map in your palette so it belongs to the page. Google's own controls and branding are theirs, not the component's.

12. Reservations

 **Reservations** is a contact box, not a form: the phone number and the e-mail address as two large tiles, with the opening hours underneath and a line of small print below that.

On a phone the tiles stack and each one is a single tap — `tel:` opens the dialler, `mailto:` opens the mail app.

There is nothing to set up and nothing that can fail: no endpoint, no account, no third-party script, and no form that thanks a guest for a reservation it never sent.

Phone and **Hours** fall back to whatever is filled in under  Find us, so the same number does not have to be typed twice. Fill these in only when the booking line differs from the one in the footer. Clearing **E-mail** hides that tile and the phone spans the card.

Small print is the line underneath — the place for a minimum group size, a deposit rule, or the hours the phone is answered.

13. Social links

 **Social links → Profiles** is a list. Each row is a network, a name, and an address. **An empty address hides that icon**, so clearing the URL is how you remove one you do not use.

The **Network** dropdown carries twenty marks — Instagram, Facebook, TikTok, YouTube, X, Threads, Pinterest, LinkedIn, WhatsApp, Messenger, Telegram, Snapchat, Spotify, Google — plus a star for a

reviews link, a map, a globe for your own site, and an e-mail glyph (use a `mailto:` address with that one).

For a service without a mark of its own — TripAdvisor, Yelp, a delivery partner — upload your logo into **Own logo** and it replaces the icon.

Look gives four styles: soft tinted tiles, solid in the button colour, outlined, or plain icons. Three switches decide where the row appears: **In header** (hidden automatically on phones, where the header has no room), **In footer**, and **In slide-out menu**, which is the one people actually find on a phone.

14. Cookie bar

 **Cookie bar** is **off out of the box**. With it off the page never touches browser storage at all. Switch **Show** on when you want it.

You set the heading, the text, both button labels and a link to your privacy page. **Position** puts it bottom centre, bottom left or bottom right; on a phone it always spans the width and stacks the buttons.

Once a visitor answers, the choice is remembered and the bar does not come back — which is a nuisance while you are styling it, so **Always show (styling)** keeps it on screen. Turn that off before publishing. On the Framer canvas the bar stays hidden unless that switch is on, so it never sits over the design while you work.

Saved under is the name the answer is stored under. Change it — say to `cookie-consent-2` — and everyone is asked again, which is what you want after the policy changes.

What it does and does not do

The bar **records a choice; it does not block anything**, and the component itself loads no analytics or tracking of any kind. If you add tracking later, gate it on the answer:

```
// "accepted", "declined", or null if nobody has answered
localStorage.getItem("cookie-consent")

window.addEventListener("cookie-consent", (e) => {
  if (e.detail.choice === "accepted") startAnalytics()
})
```

Shipping a bar is not the same as being compliant. What makes a site lawful is not loading the trackers until consent exists, and saying in your privacy page what you collect. The bar gives you the switch; wiring it up is yours.

15. Photo sizes

WHERE	RECOMMENDED	NOTES
Hero ( Hero)	2000 × 1100 px	Landscape. Leave room on one side for the writing.
Menu tiles ( Menu)	900 × 820 px	Nearly square. Cropped to fill the tile.
Gallery ( Gallery)	900 × 500 px	Landscape.
About ( About)	1200 × 780 px	Landscape. Leave empty for the icon.
Own social logo ( Social)	128 × 128 px	PNG or SVG, transparent.

These are roughly twice the size the photo is shown at, which keeps it sharp on phones and high-resolution laptops. Bigger than this only makes the page slower.

The five photographs in `photos/` are the ones from the demo, ready to upload: `hero-spaghetti-bolognese.jpg` for the hero, and `menu-01-starters.webp` through `menu-04-main-plate.webp` for the first categories.

16. On a phone

The layout does not follow the browser window — it follows the width of the component itself, measured as the page is drawn. That matters in Framer, because a phone breakpoint on a wide canvas is still a narrow component in a wide window, and an ordinary media query would give it the desktop layout.

What changes as it narrows:

- the navigation links give way to the menu button
- the header's social icons hide, where there is no room for them
- the hero stacks: photograph above, writing below on a dark panel
- the menu tiles go to one column
- the dish panel becomes nearly full-screen with larger type
- the contact tiles stack
- the cookie bar spans the width and stacks its buttons

17. The HTML version

`zelena-vinice-mockup.html` is the same site as one self-contained file. Fonts, photographs, styles and scripts are all inside it — there is nothing to link and nothing to install.

Use it to show a client the design before they commit, to host the site on plain shared hosting or on Netlify, Vercel or GitHub Pages, or to edit the design by hand if you prefer code to a visual editor.

To publish it, rename the file to `index.html` and upload it. That is the whole deployment.

Opening it on a phone

Tapping the file in a phone's Files app often opens a *preview* rather than a browser, and those previews do not run scripts. For the full experience open the file in a real browser. On iPhone: share icon → **Open in Safari**. On Android: open it from Chrome rather than the file manager.

18. Moving the template to another restaurant

Nothing in the layout is specific to this one. The route is always the same:

1. 🎨 **Colors** — pick the theme nearest the room, then override the one or two colours that are actually yours.
2. 📶 **Header** and 🏠 **Footer** — the name, in two halves.
3. 🖼️ **Hero** — one good photograph of a plate or the room.
4. 🍽️ **Menu** — rename the categories, upload a photograph for each, and fill in the dishes.
5. 📍 **Find us** and 📅 **Reservations** — the address, the hours, the phone.
6. Switch off any section you do not need.

A bistro, a wine bar, a pizzeria and a hotel restaurant all come out of this same file.

19. If something looks wrong in Framer

The page is cut off at the bottom. The frame around the component has a fixed height. Set it to **Fit content** on that breakpoint. The component itself never clips its own content.

A setting is missing from the panel. Check the **Version** field first — see section 2.

The layout is desktop-shaped inside a narrow frame. It should not be: the breakpoints read the component's own width. If it happens, the frame is wider than it looks.

Opening hours are all on one line. Section 4 — use a `|`.

20. Notes

- The map is a Google Maps embed. It needs an internet connection, so it stays blank in offline previews and loads normally on a live page.
- The icons are drawn into the component rather than fetched from a font service, so they work offline and take your palette colour.
- The site respects the visitor's reduced-motion setting: transitions stop and the hero parallax holds still.
- Photographs are embedded directly in the HTML file, which is why it is large. That is the trade for it being self-contained.
